### Peter Williams

#### Section 1.1

Exercise 1. Consider the linear regression model with mean zero, uncorrelated, heteroscedastic noise:

$$Y_i = X_i^{\mathsf{T}}\theta + \varepsilon_i, \text{ for } i = 1, ..., n, \ E\varepsilon_i = 0, \ cov(\varepsilon_i, \varepsilon_j) = \begin{cases} \sigma_i^2, & \text{if } i = j \\ 0, & i \neq j \end{cases}$$
 (1)

Find expressions for the LSE and response estimator in this model

Under heteroscedastic noise assumptions, the LSE estimator, denoted  $\hat{\theta}_{OLS}$ , is:

$$\hat{\theta}_{OLS} = \underset{\theta}{argmin} ||Y - X^{\mathsf{T}}\theta||^2 = \underset{\theta}{argmin} \ G(\theta)$$

$$||Y - X^\intercal \theta||^2 = G(\theta) = (Y - X^\intercal \theta)^\intercal (Y - X^\intercal \theta) = YY^\intercal - 2\theta^\intercal XY + \theta^\intercal XX^\intercal \theta$$

with gradient,

$$\nabla G(\theta) = -2XY + 2\theta^{\mathsf{T}}XX^{\mathsf{T}}$$

Setting this expression equal to zero leads to estimator  $\hat{\theta} = \hat{\theta}_{OLS} = (XX^{\dagger})^{-1}XY$ , which leads to response estimator  $\hat{Y} = X^{\dagger}\hat{\theta} = X^{\dagger}(XX^{\dagger})^{-1}XY$ .

Exercise 2. Assume that  $\varepsilon_i \sim N(0, \sigma_i^2)$  in the previous problem. What is known about the distribution of  $\hat{\theta}$  and  $\hat{Y}$ ?

Denote  $n \times n$  matrix  $D = diag\{\sigma_1^2, \sigma_2^2, ..., \sigma_n^2\} = Var(\varepsilon)$ .

For  $\hat{\theta}$ , we have,

$$E[\hat{\theta}] = E[(XX^\intercal)^{-1}XY] = E[(XX^\intercal)^{-1}X(X^\intercal\theta^* + \varepsilon)] = E[\theta^*] + E[\varepsilon] = \theta^*$$

indicating that  $\hat{\theta}$  is unbiased despite the presence of heteroscedastic noise. Further  $\hat{\theta}$  is normally distributed, since is a linear transformation of  $\varepsilon \sim N(0, D)$ . Further we have,

$$Var(\hat{\theta}) = Var((XX^{\mathsf{T}})^{-1}XY) = Var((XX^{\mathsf{T}})^{-1}X(X^{\mathsf{T}}\theta^* + \varepsilon)) = Var((XX^{\mathsf{T}})^{-1}X\varepsilon)) = (XX^{\mathsf{T}})^{-1}XVar(\varepsilon)X^{\mathsf{T}}(XX^{\mathsf{T}})^{-1} = (XX^{\mathsf{T}})^{-1}XDX^{\mathsf{T}}(XX^{\mathsf{T}})^{-1} = Var(\hat{\theta})$$

For  $\hat{Y}$  we have,

$$E[\hat{Y}] = E[X^{\mathsf{T}}(XX^{\mathsf{T}})^{-1}XY] = E[X^{\mathsf{T}}(XX^{\mathsf{T}})^{-1}X(X^{\mathsf{T}}\theta^* + \varepsilon)] = E[X^{\mathsf{T}}\theta^* + X^{\mathsf{T}}(XX^{\mathsf{T}})^{-1}X\varepsilon] = E[X^{\mathsf{T}}\theta^*] = Y$$
 and,

$$\begin{split} Var[\hat{Y}] &= Var[X^\intercal(XX^\intercal)^{-1}XY] = Var[X^\intercal(XX^\intercal)^{-1}X(X^\intercal\theta^* + \varepsilon)] = Var[X^\intercal\theta^* + X^\intercal(XX^\intercal)^{-1}X\varepsilon] = \ \dots \\ &\dots = Var[X^\intercal(XX^\intercal)^{-1}X\varepsilon] = X^\intercal(XX^\intercal)^{-1}XVar(\varepsilon)X^\intercal(XX^\intercal)^{-1}X = \Pi D \Pi^\intercal \end{split}$$

where 
$$\Pi = X^{\intercal}(XX^{\intercal})^{-1}X = \Pi^{\intercal}$$
, and  $D = diag\{\sigma_1^2, \sigma_2^2, ..., \sigma_n^2\}$ .

Now suppose additionally that  $\sigma_i^2 \equiv \sigma^2 > 0$ . What can be said about distribution of the estimator  $\hat{\sigma}^2$ ? Insert solution here

Exercise 3. Consider the linear regression model from exercise 1. Suppose, that the target of estimation is  $h^{\dagger}\theta$  for some determinate non-zero vector  $h \in R^p$ . Find expression for the LSE of  $h^{\dagger}\theta$ . Is this estimate optimal in sense of Gauss-Markov theorem, i.e. does it have the smallest variance among all linear unbiased estimators?

—Start with this —By Gauss Markov, we know that a BLUE estimator has  $Var(\theta_{OLS}) = \sigma^2(XX^{\dagger})^{-1}$ . However in the case of heterscedastic noise, we have  $Var(\theta) = (XX^{\dagger})^{-1}XDX^{\dagger}(XX^{\dagger})^{-1}$ , which must be greater than  $\sigma^2(XX^{\dagger})^{-1}$ ). An so, in this case, our estimator is not BLUE. Study the same issue for the target  $\eta = H^{\dagger}\theta$ , where  $H \in \mathbb{R}^{q \times p}$  is some non-zero matrix with  $q \leq p$ .

#### Section 1.3

Exercise 4. Let  $A \in R^{n \times n}$  be a matrix (corresponding to a linear map in  $R^n$ ). Show that A preserves length for all  $x \in R^n$  iff it preserves the inner product. I.e. one needs to show the following:  $||Ax|| = ||x|| \, \forall \, x \in R^n \iff (Ax)^{\intercal}(Ay) \, \forall \, x, y \in R^n$ .

$$||x|| = \sqrt{x \cdot x} = \sqrt{x^{\mathsf{T}} x} \implies ||Ax|| = \sqrt{Ax \cdot Ax} = \sqrt{x^{\mathsf{T}} A^{\mathsf{T}} Ax} \implies$$
$$A^{\mathsf{T}} A = I_n = A^{-1}, \ A^{\mathsf{T}} = A^{-1}, ||Ax|| = ||x||$$

this implies A is an orthogonal matrix, and further,

$$(Ax)^{\mathsf{T}}(Ay) = ||AxAy||^2 = x^{\mathsf{T}}A^{\mathsf{T}}Ay = x^{\mathsf{T}}y = ||xy||^2$$

Exercise 5. (a) Let  $x_0 \in R^n$  be some fixed vector, find a projection map on the subspace  $span(x_0)$ . Compare your result with matrix  $\Pi$  (from section 1.3) for the case of p=1. (b) Prove part 3) of Lemma 1.1 for an arbitrary orthogonal projection in  $R^n$ . Exercise 6. Let L1, L2 be some subspaces in  $R^n$ , and  $L2 \subseteq L1 \subseteq R^n$ . Let PL1, PL2 denote orthogonal projections on these subspaces. Prove the following properties: (a) PL2-PL1 is an orthogonal projection, (b)  $|PL2| \leq |PL1| \ \forall x \in R^n$ , (c)  $PL2 \cdot PL1 = PL2$ 

## Section 2.1

Exercise 7. (a) Using the notation from section 2.1, consider  $X \sim N(\mu, I_n)$  for some  $\mu \in \mathbb{R}^n$ . Find EQ(X) and VarQ(X). (b) Generalize the results from part (a) to the case  $X \sim N(\mu, \Sigma)$  for some positive-definite covariance matrix  $\Sigma \in \mathbb{R}^{n \times n}$ .

Exercise 8. Let  $X \sim N(0, In)$ , Q = XX. Suppose that Q is decomposed into the sum of two quadratic forms: Q = Q1 + Q2, where  $Qi = X^{\mathsf{T}}A_iX$ , i = 1, 2 for some symmetric matrices A1, A2 with rank(A1) = n1 and rank(A2) = n2. Show that if n1 + n2 = n, then Q1 and Q2 are independent and  $Q_i \sim \chi^2(n_i)$  for i = 1, 2.

#### Section 2.2

Exercise 9. In the Gaussian linear regression model 3, consider the target of estimation  $\eta = H^{\intercal}\theta^*$ , where  $H \in R^{q \times p}$  is some non-zero matrix with  $q \leq p$ . Find an analogue of the quadratic form S2 (from (4)) for the new target  $\eta^*$ , and prove for the new quadratic form statements similar to (e) from Theorem 2.1, and Corollary 2.1.2.

Exercise 10. (a) Consider model (3) for  $p = 2, X_i = (1, x_i)^{\mathsf{T}}, \theta^* = (\theta_1^*, \theta_2^*)^{\mathsf{T}}$  (similarly to section 1.5). Write explicit expressions for the confidence sets for  $\theta^*, \theta_1^*, \theta_2^*$ .

(b) Find a confidence interval for the expected response  $E[Y_i]$  in the model in part (a).

Exercise 11. Find an elliptical confidence set for the expected response E[Y] in model (3).

Exercise 12. Construct simultaneous confidence intervals (e.g., as in Corollary 2.2.1) for the expected responses  $E[Y_1], ..., E[Y_n]$  in model (3).
